AI-Powered Knowledge & Tasks Management Platform

30 Oct 2026 · SPIT Assignment

DigiPlus Technical Assessment • Duration: 3.5 Hours

Problem Statement

Teams lose context every time work changes hands. Someone misses a meeting or never responds to the invite; a colleague goes on leave, or an action item from last week's meeting never makes it onto this week's agenda. Build a small AI-powered application that captures what was discussed and decided, transfers that context to the right people, and follows up on open items until they are closed. This information can be scattered around in documents, personal notes, chats, meeting recordings, or emails

Outcome:

- Create and persist meetings or work transfers: agenda, participants, notes, decisions and action items.
- View and manage their lifecycle, and track every action item (example fields: owner, due date, status) until it is closed.
- Carry open items forward to the next meeting or work transfer, keeping their history.
- Use AI to turn raw unstructured info into a structured recap: summary, decisions, action items and owners.
- Give anyone who missed the meeting, or is taking over, a short AI-generated catch-up brief.
- Maintain a small knowledge base (team documents, past meetings) and use AI to link items to it.
- Record the outcome of each item.
- Include appropriate validation and error handling.

AI Requirement

AI must be a meaningful part of the solution. The model/provider, prompts and data flow are your choice. Do not rely entirely on hard-coded rules, and handle AI failures gracefully.

Logging

Implement structured application logging: proper log levels, a correlation/request ID per request, key events (created, reassigned, item closed), AI calls with latency and outcome, errors with context, output written to a file, and no secrets in logs.

Make It Special

Implement at least one feature of your own that makes your solution stand out. Choose it and build it as per your understanding of the problem and explain in your README why it adds value.

Your Approach

UI, architecture, technology stack, database schema and API design are not prescribed. Make your own technical decisions and document it.

Submission

Source code and a README covering AI configuration, data source, logging setup, your special feature, a short explanation of your approach, assumptions and known limitations. Deploy the application to a suitable server.

Assessment Focus

Area	Focus
Functionality	Working and coherent solution
AI	Appropriate use, reasoning and reliability
Engineering	Design, code quality and maintainability

Data	Quality of your own data; persistence and sensible handling
Logging	Structured, traceable and useful logs
Originality	Value and execution of your special feature
UX	Clarity and usability

AI coding assistants may be used. You must be able to explain your implementation and decisions.
